

The following is a list of important points from the video Object Oriented Programming:

- Introduction to Programming
- A computer program is a set of instructions that a computer carries out to do a job.
- A procedural program is a list of actions or instructions for the computer, similar to following a recipe.
- Key Concepts of Object-Oriented Programming (OOP)
- OOP is a technique that uses objects to organize properties and methods into one unit.
- Class
- The blueprint or model for an object (e.g., the “Baker” class).
- Object
- An instance created from a class (e.g., creating a “cakeman” object from the “Baker” class).
- Objects contain all the necessary information, including properties (tools/ingredients/data)
- and methods (actions/instructions).
- Abstraction
- Hiding details by placing them inside the class, so you only have to think about the overall task the object needs to perform (e.g., calling a bake cake method without knowing every step).
- Code Reuse
- Allows you to use a single class model to create multiple objects (e.g., “cakeman” and “pieman”), reusing the underlying computer instructions.
- Encapsulation (Information Hiding)
- Objects created from the same class have the same properties and methods, but their properties are private and cannot be accessed by other objects.
- Parameters
- Terms defined in the class declaration (e.g., what breed, what size) that allow you to specify the initial properties when a new object is created.
